Freiberg, Germany*

June 20th, 2018

# Constructing the 3D model

- Based on crustal-scale tectonic 3D model by Freiberg University
- 278 maps (geologic, tectonic, isoline and mining maps)
- 312 profile sections (incl. seismic profiles)
- c. 6700 wells (20 to 1700 m depth)
- Gravity, airborne magnetic and gamma-spectroscopy legacy data

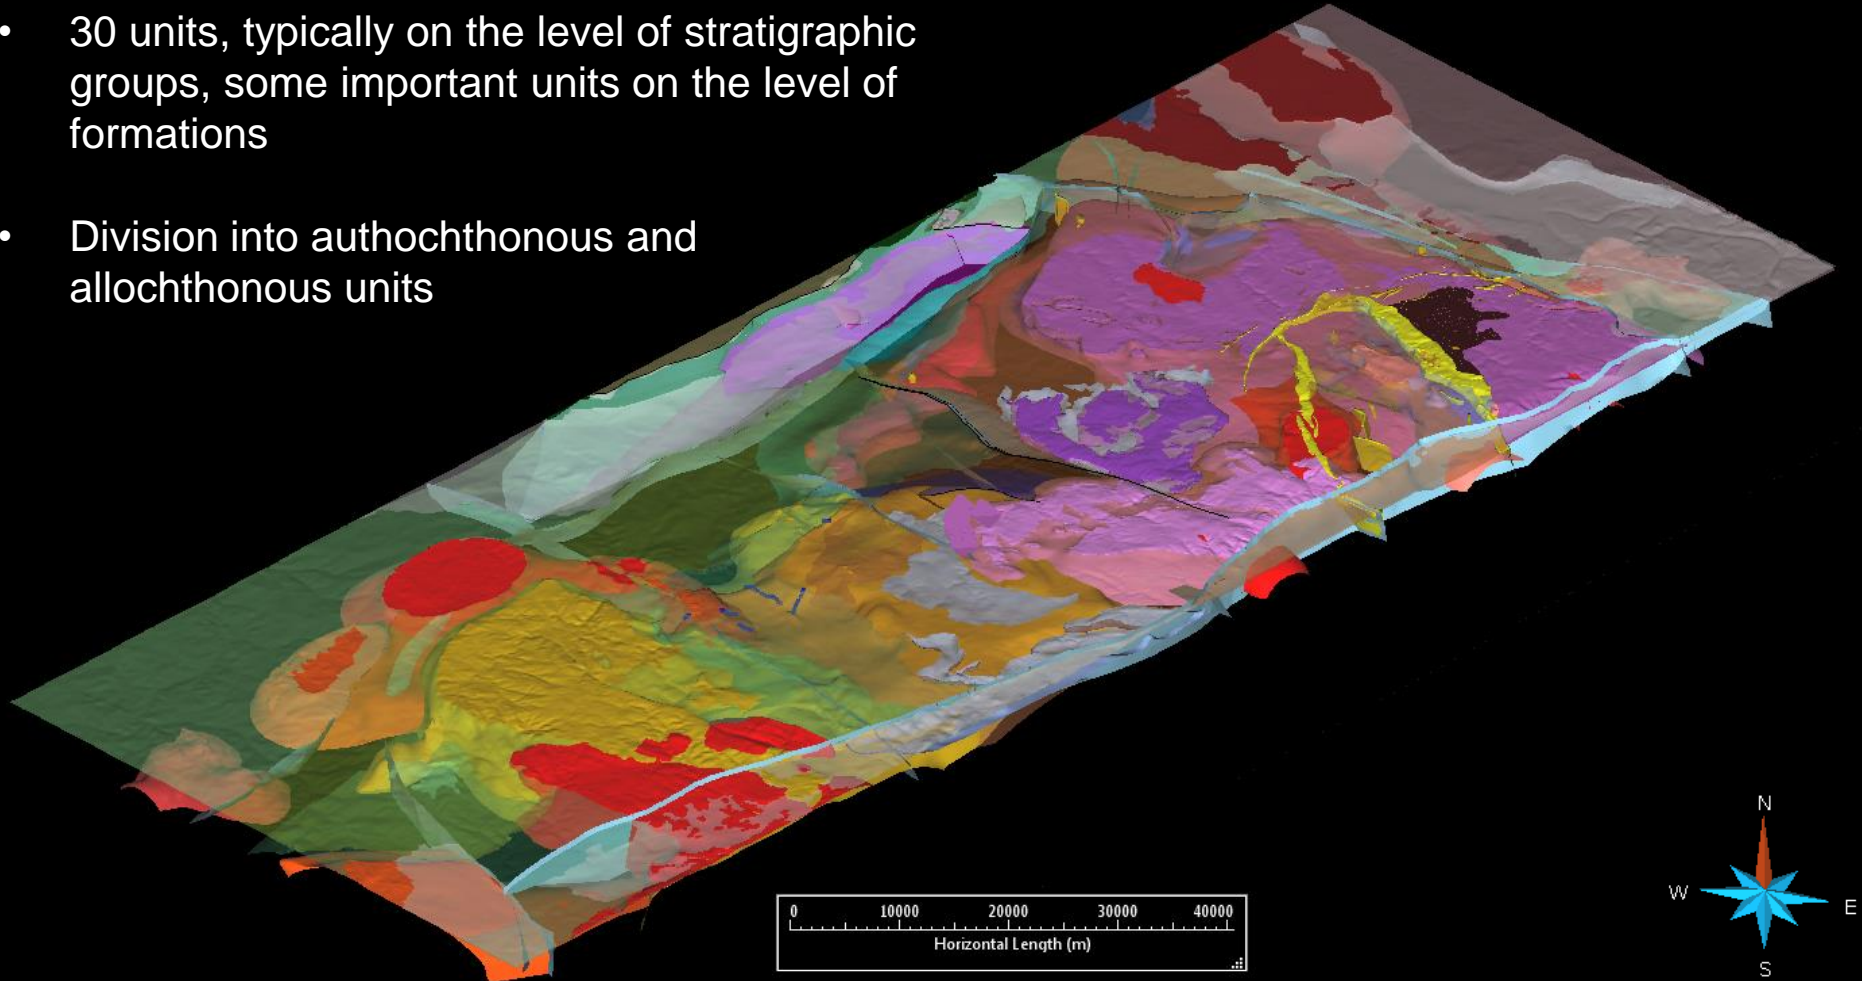

# Constructing the 3D model

## Cover units (sediments and metamorphics)

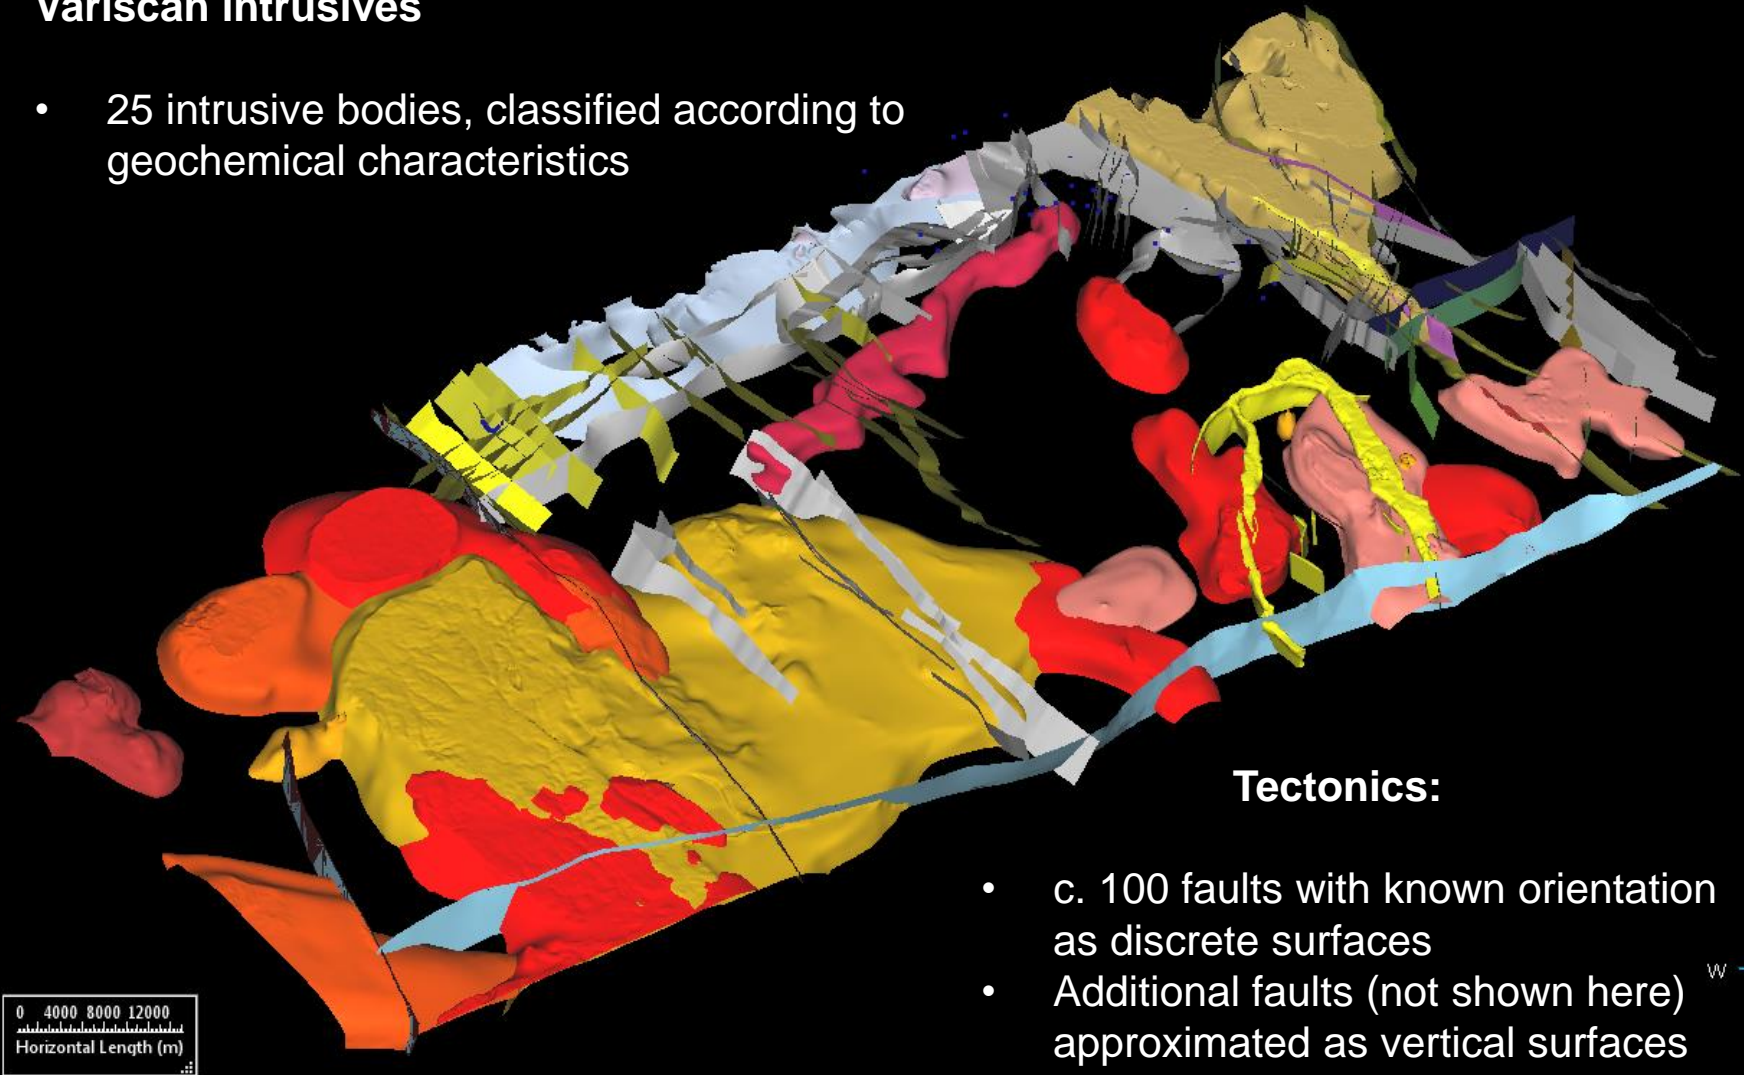

- 30 units, typically on the level of stratigraphic groups, some important units on the level of formations
- Division into autochthonous and allochthonous units

# Constructing the 3D model

## Variscan intrusives

- 25 intrusive bodies, classified according to geochemical characteristics

# Constructing the 3D model

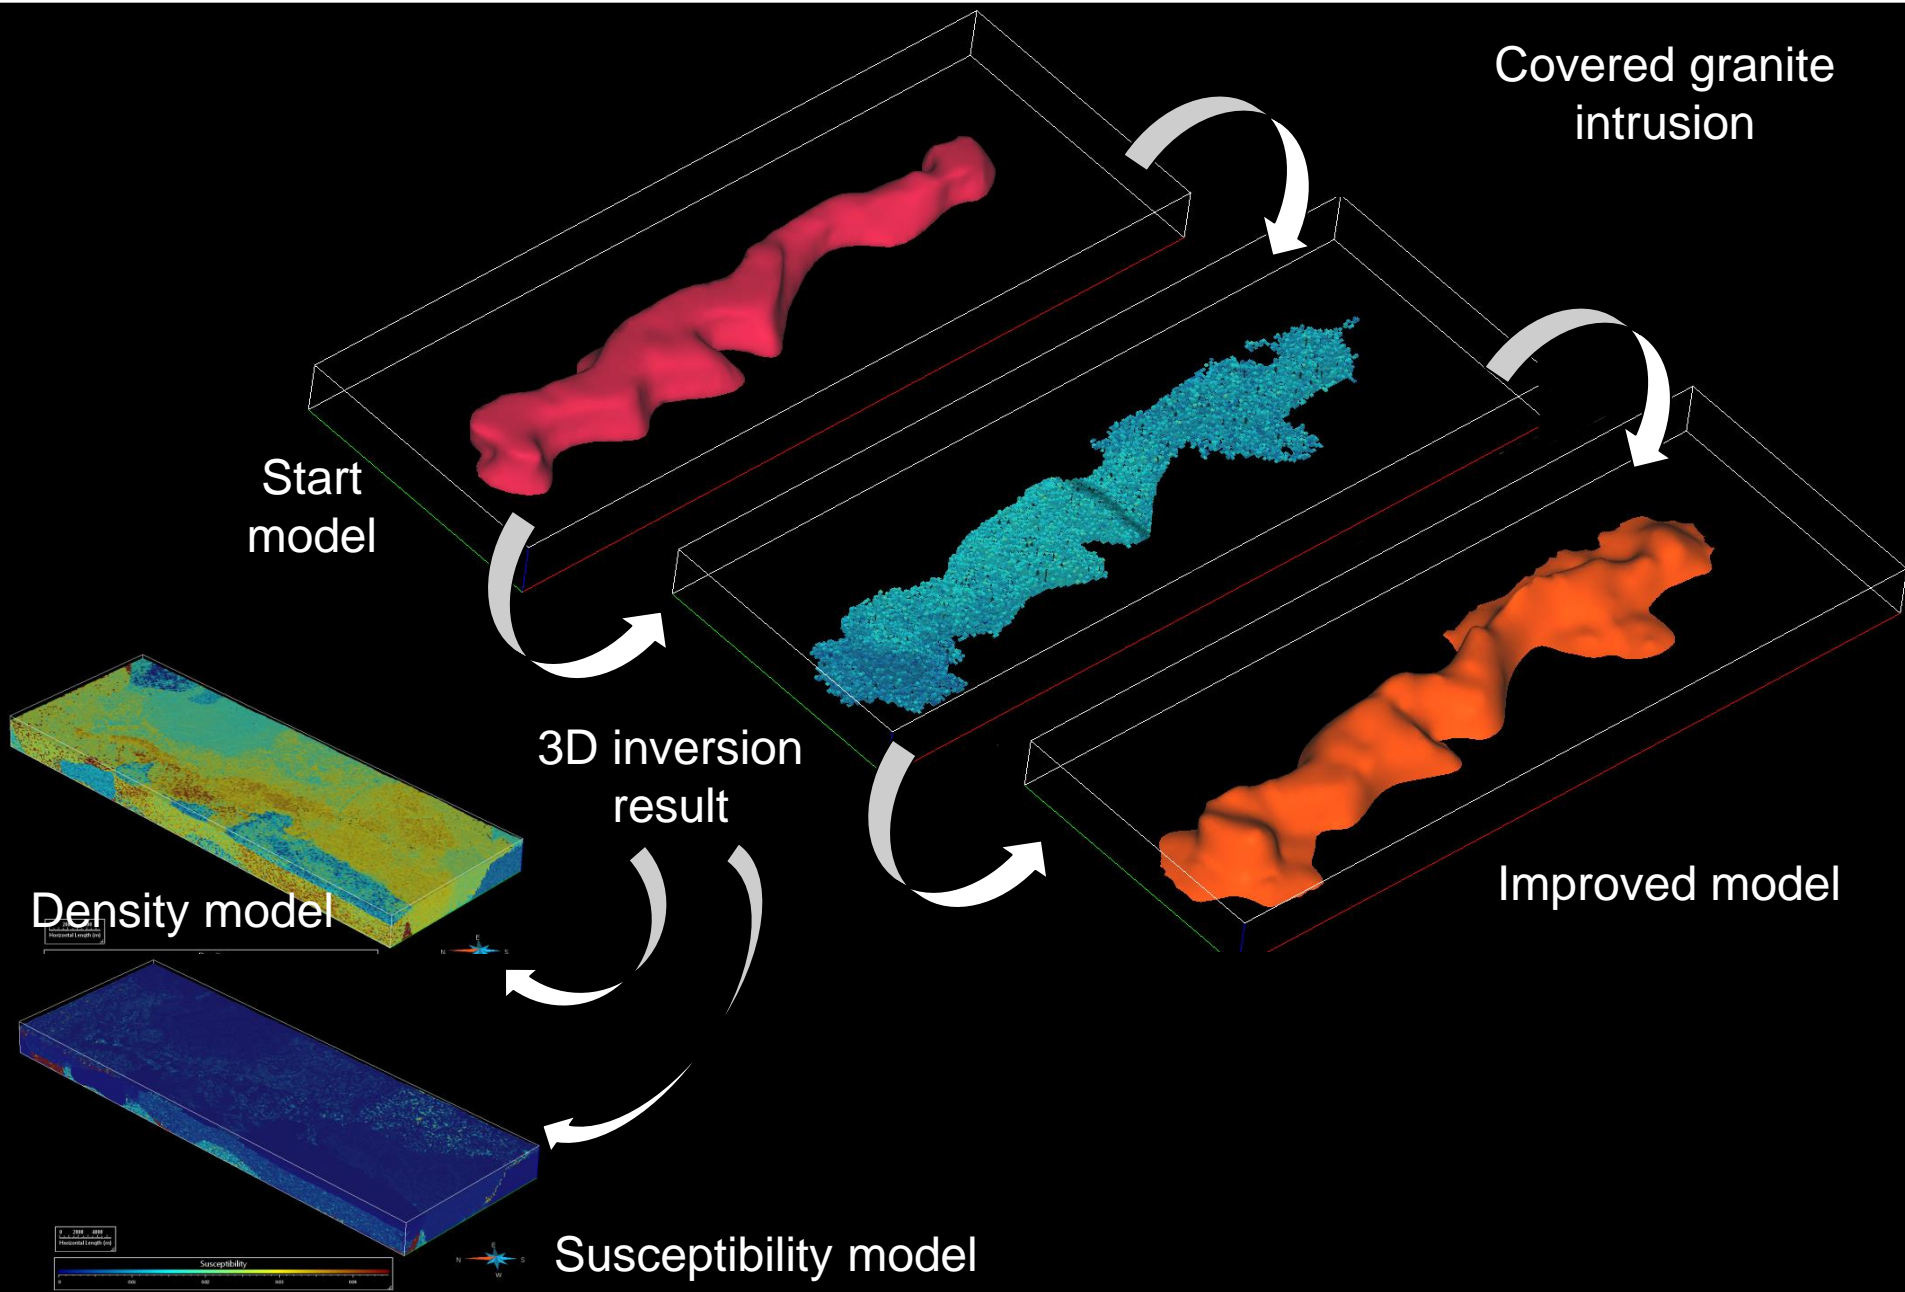

## Covered intrusions

3D inversion of gravity and magnetic data to improve the 3D model

→ Selection of a 80 x 20 km test area for 3D mineral potential modelling

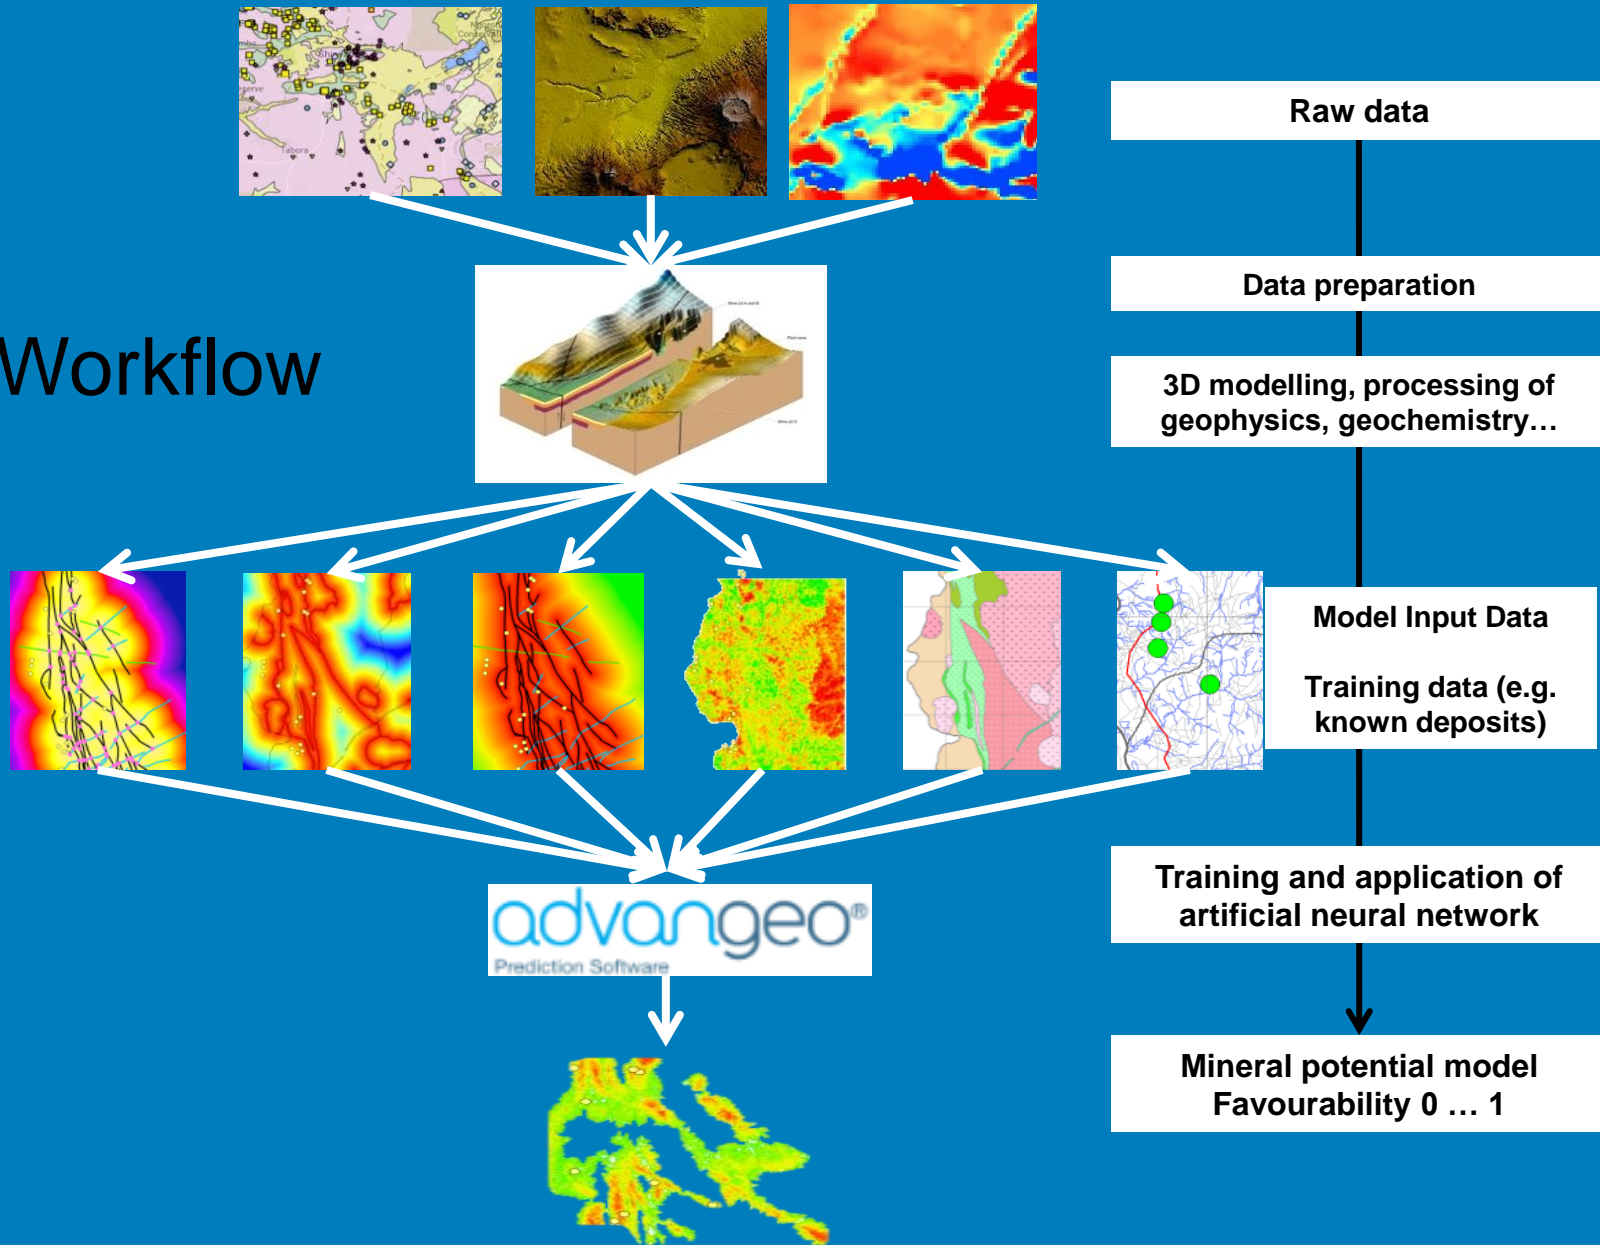

# Constructing the 3D model

# Mineral potential modelling with ANN

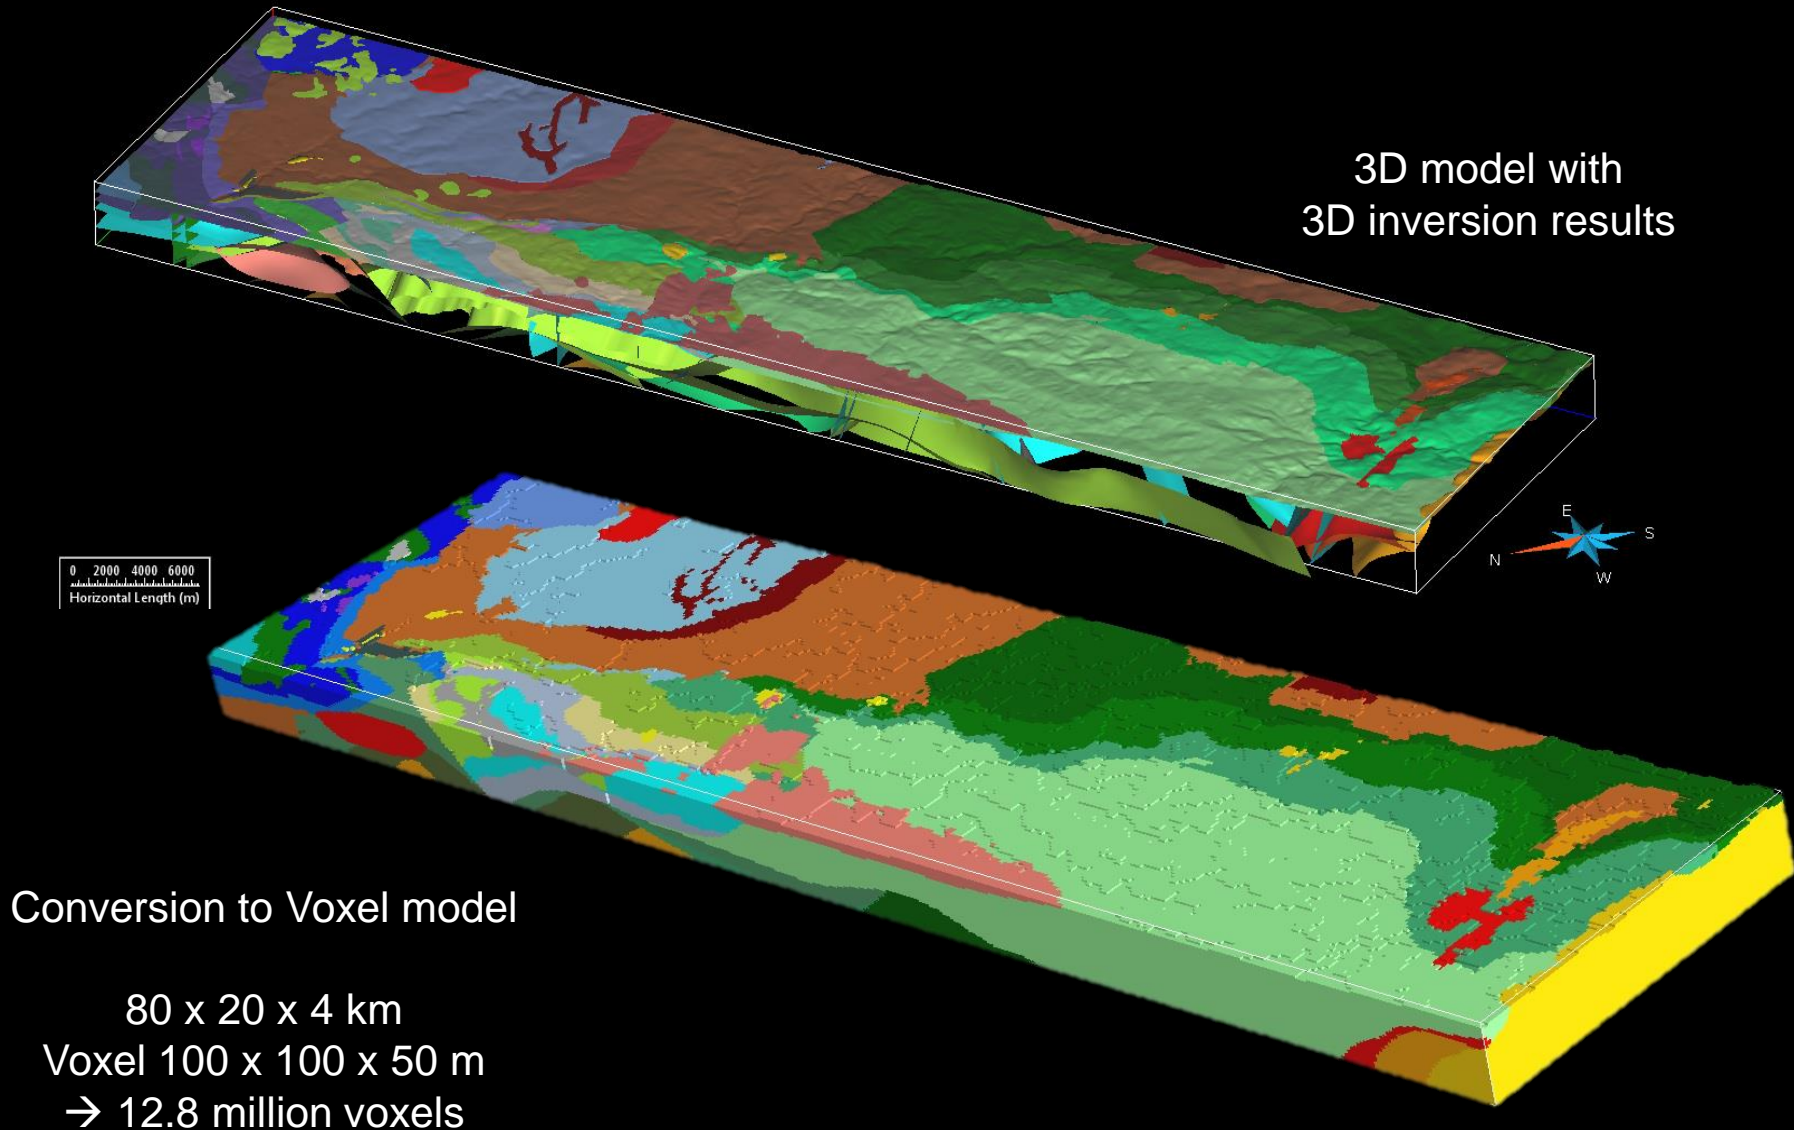

## Workflow

# Mineral potential modelling with ANN

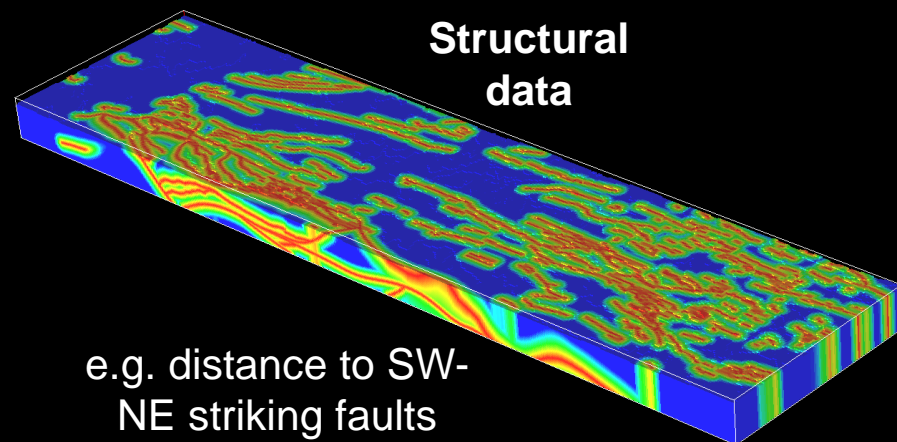

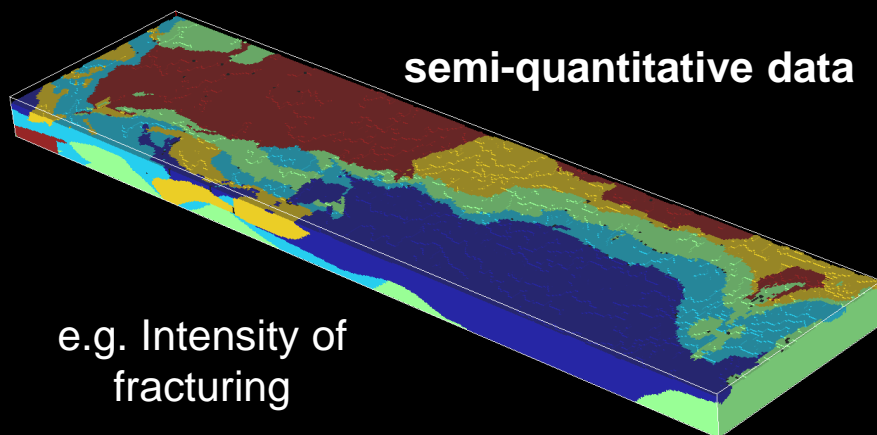

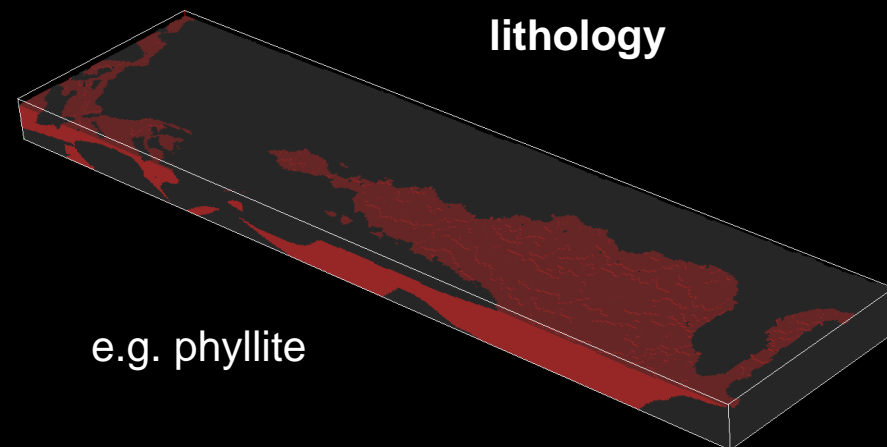

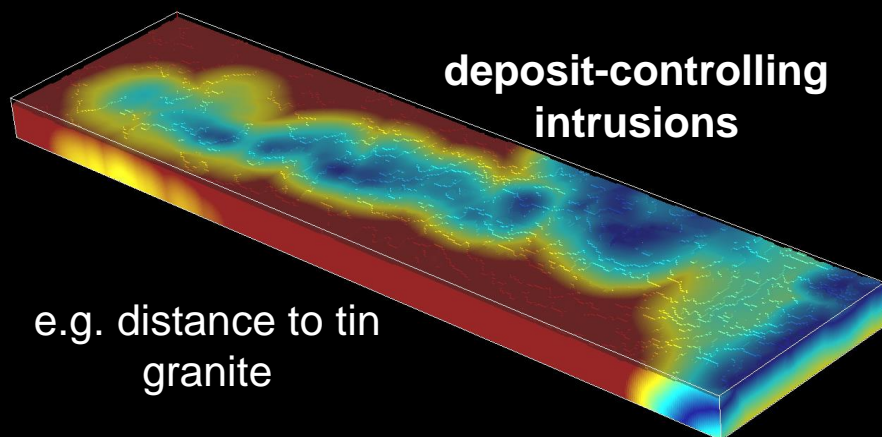

## Preparation of 3D model for ANN

# Mineral potential modelling with ANN

## Examples of model input data for 3D mineral potential modelling

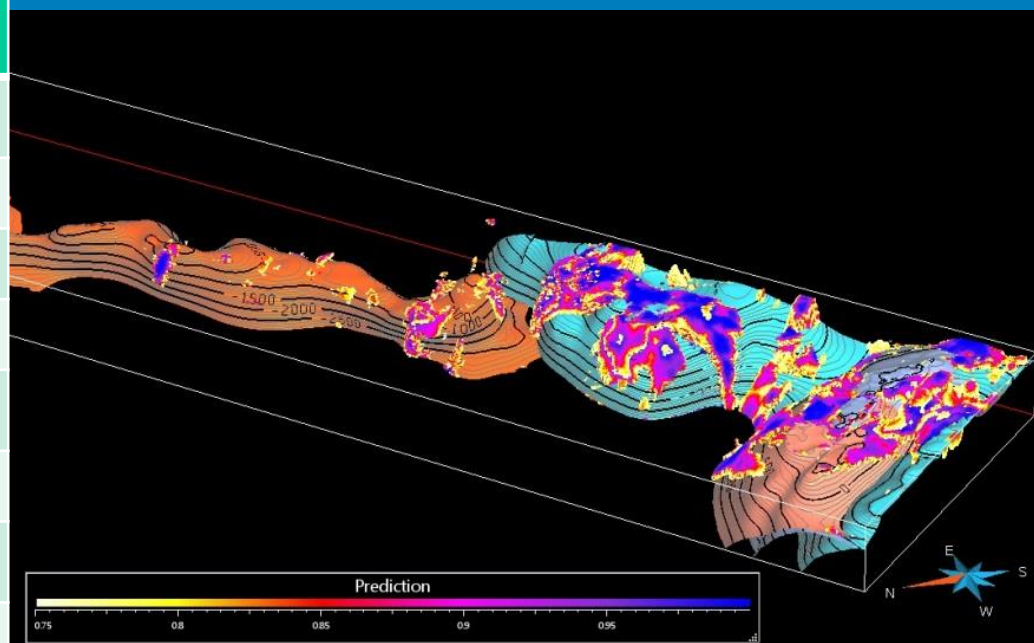

Also: density model, susceptibility model, stratigraphy, geochemistry, derivatives of geophysical data ...

# Mineral potential modelling with ANN

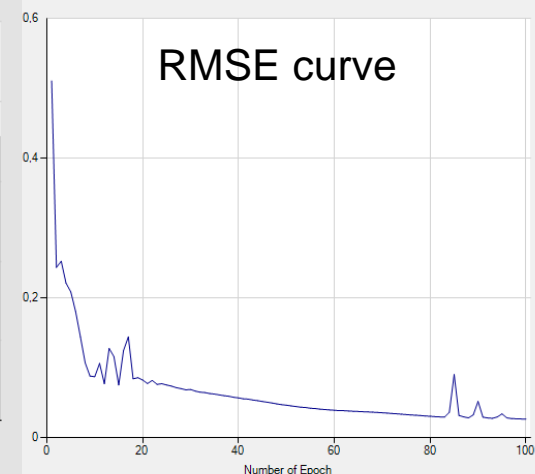

## Weights of model input data

Model Input Data (MID)	Connection Weights	Garsons' Algorithm
Distance to granite type Eibenstock	107,14	5,14
Extent of granite	-590,37	3,25
Aeromagnetics DeltaT Slope	-1922,43	3,24
Distance to very large faults	-498,07	3,17
Distance to Geological Units – Thum Group	-433,56	2,44
Gravimetry Gradient	-741,45	2,13
Distance to faults of high sinuosity	-324,36	2,07
...	...	...

## Mineral potential model for vein-hosted tin

**Indication of predictive power**

# Reproducibility and variance

9 copies of the same model, showing voxels with favourability  $>0.75$

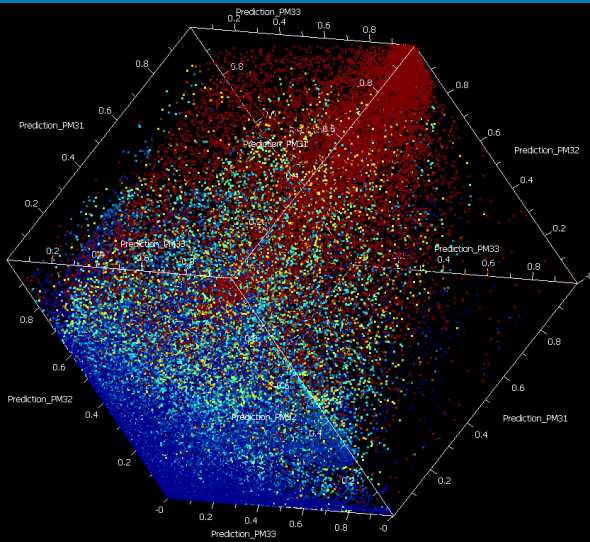

→ Some „core volumes“ have high potential in every model, „peripheral volumes“ have high potential in some models, less potential in others

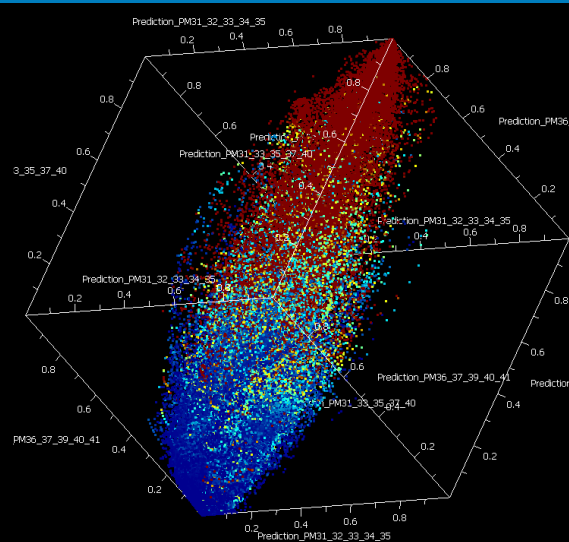

# Reproducibility and variance

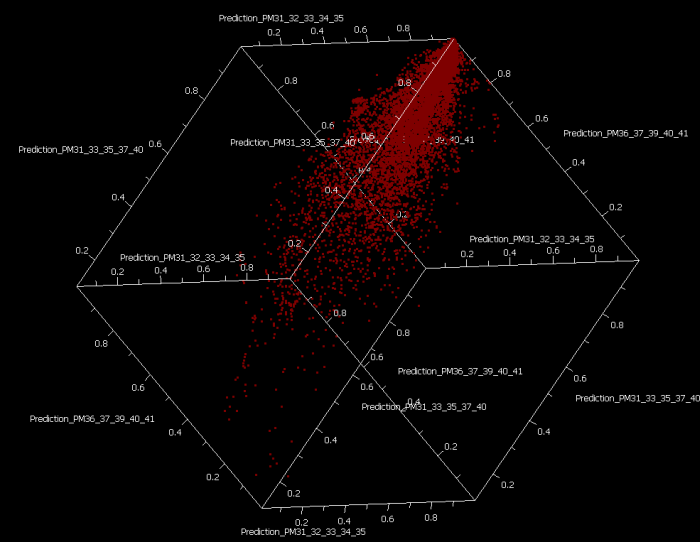

Cube plot of favourabilites from three copies of the same model

All voxels

Only „core volumes“

Only „core volumes“,  
only favourability > 0.75

- „core volumes“ have high reproducibility
- „peripheral volumes“ are concentrated in parts of the 3D model that are less constrained by input data

→ Variance of favourability over repeated model runs can be used to assess prediction uncertainties

# Exploration Targeting / Field verification

Selection of near-surface high potential volumes for field reconnaissance

Chloritized micaschist with finely disseminated cassiterite at the Amsberg locality

Measured by handheld XRF

# Conclusions: 3D Mineral potential modelling with ANN

- 3D predictive modelling results in volumes of interest and their depth below surface  
→ **exploration targeting** greatly improved compared to 2D predictive maps
- **Model uncertainty** (2D and 3D) can be evaluated by repeated training of the artificial neural network and analysis of variability  
→ exploration targets can be ranked for model uncertainty
- Requires enough information to construct 3D model and training data  
→ best suited for **brownfields exploration**
